The massive, underserved gap in computational electromagnetics education

Computational electromagnetics education is stuck in the 1990s while the field races ahead. Across Reddit, Stack Exchange, Amazon reviews, and engineering forums, students and practitioners express a consistent frustration: CEM resources are either impenetrably theoretical or locked behind $50,000+ commercial tool ecosystems, with almost nothing in between. No major MOOC platform (Coursera, edX) offers a single CEM implementation course. The lone comprehensive free option is an Indian NPTEL course with limited global reach. Meanwhile, employers list **1,000+ open CEM-related positions** in the US alone at salaries of $100K–$190K, and the field expands rapidly with 5G/6G, autonomous vehicle radar, and AI-driven design. This report identifies and ranks 15 specific educational gaps by demand signal strength and underservice level, backed by forum posts, reviews, and market data.

The "valley of death" between theory and implementation

The single most consistent finding across all research channels is a chasm between textbook EM theory and practical CEM implementation. Dr. Raymond Rumpf, creator of EMPossible (the only dedicated CEM educator online), captured it precisely: **"The majority of the materials I found assumed that I already knew a lot about those topics — and I didn't. There were no materials out there for someone just getting started."** EMPossible EMPossible His students echo the sentiment: "Your videos fill a gap between basic university courses and scientific papers on EM topics." EMPossible On Physics Forums, a user cataloging their frustration wrote: "I have a lot of engineering EM books, from the easiest one by Ulaby to more difficult ones like Cheng, Hyatt. **None really explain EM that well.**" Physics Forums

This gap manifests in three specific ways. First, **textbooks are single-method and code-free**: Taflove covers only FDTD, Jin covers only FEM, Harrington covers only MoM — and none provide runnable code (except Davidson's book, which uses MATLAB). Students must purchase 3–4 books at $80–$200 each for coverage that still lacks implementation guidance. Amazon reviewers of Balanis's *Advanced Engineering Electromagnetics* note "sometimes you can lose sight of the big picture amidst all of the math" and "coming from EE, I found it difficult to simply read this book... he uses big words when he doesn't need to." Amazon Sadiku's *Numerical Techniques* is criticized for introducing MoM and FEM "through variational methods, which is probably an elegant yet unintuitive way to understand them." Amazon

Second, **university courses stop at 2D MATLAB scripts**. A survey of CEM courses at MIT, Stanford, Purdue, UIUC, Georgia Tech, and Michigan reveals that while most require "computer projects," these are typically simple 1D/2D MATLAB exercises. No course teaches GPU acceleration, ML integration, open-source tools, hybrid methods, or software engineering practices for CEM code. UIUC's ECE 540 (taught by Jin himself) requires "development of rudimentary computer codes," University of Illinois ECE and Georgia Tech's ECE 6380 mandates "computer projects" Georgia Tech Georgia Tech — but the leap from rudimentary to production remains unbridged.

Third, **no clear learning pathway exists**. On Physics Forums, a junior EE major asking "How to learn computational electromagnetics?" received advice to separately study Fortran/C++, numerical analysis, and

computational physics (Physics Forums) — illustrating that **no integrated curriculum connects programming, numerical methods, and EM theory into CEM competence**.

Prioritized gap ranking by demand and underservice

The following ranking synthesizes community complaints, search volume analysis, job posting frequency, and resource availability into a combined score. Each gap is assessed on two dimensions: **demand signal strength** (how many people want this, evidenced by forum posts, job requirements, and search activity) and **underservice level** (how poorly current resources address it).

Tier 1: Critical gaps with strong demand signals

1. Python-based CEM implementation courses (FDTD, MoM, FEM from scratch)

- Demand: HIGH — Python dominates scientific computing; every CEM job posting lists Python/MATLAB
- Underservice: EXTREME — **Zero** structured Python CEM courses exist anywhere. All existing courses (EMPossible, NPTEL, textbooks) use MATLAB exclusively
- Evidence: GitHub repos like (flaport/fdtd) (PyTorch backend) (GitHub) and (ymahlau/fdtdx) (JAX) show community demand for Python CEM. Multiple Reddit threads ask for Python EM resources
- Market gap: Sits between free YouTube ($0) and EMPossible paid courses (MATLAB-only, ~$50–200)

2. Practical MoM implementation with modern code

- Demand: HIGH — MoM underpins commercial tools (FEKO, NEC-2, ADS MoM); foundational for antenna/RCS work
- Underservice: EXTREME — Harrington's foundational text (MIT OpenCourseWare) dates from **1968** (Wikipedia) with zero code. (Amazon) No video tutorial series exists. No modern Python/MATLAB implementation tutorial walks through Green's functions, RWG basis functions, and impedance matrix assembly
- Evidence: EDAboard threads show students repeatedly asking for MoM coding guidance; Gibson's textbook exists but is dense and theoretical. GitHub has minimal MoM educational code
- Specific gap: The journey from "I understand the integral equation" to "I can compute the RCS of a wire antenna" has no tutorial bridge

3. Comprehensive CEM course on a major MOOC platform

- Demand: HIGH — Coursera's KAIST Electrodynamics Specialization has **15,128+ enrollments** and 4.8★ ratings, proving demand for EM education. CEM is the natural next step

- Underservice: EXTREME — **Zero** CEM courses on Coursera, edX, or Skillshare. The only MOOC option is NPTEL/IIT Madras (India-focused, limited accessibility)
- Evidence: Udemy has ~15 antenna simulation courses but none teaching CEM algorithms. The platform gap between a $10 Udemy CST tutorial and a $4,000+ Johns Hopkins graduate course is enormous

4. ML/AI integration with CEM (PINNs, surrogate models, neural operators)

- Demand: HIGH and rapidly growing — IEEE TAP ran a Special Issue on ML in antenna design; job postings increasingly require ML+CEM skills; Nature reports 160,000× speedup using deep learning surrogates
- Underservice: EXTREME — **Zero** beginner-friendly tutorials exist despite dozens of IEEE papers. No course bridges ML engineers into CEM or teaches CEM practitioners to use ML
- Evidence: Research is exploding (physics-informed neural networks for Maxwell's equations, arXiv surrogate models for antenna optimization, differentiable EM simulators Wiley Online Library like meent), but education is nonexistent
- Specific gap: A PhD student can read papers on PINNs for EM but cannot find a single tutorial to implement one

5. Simulation-to-measurement correlation workflows

- Demand: HIGH — Practitioners consistently identify this as the #1 missing skill. A student on EDAboard: **"When I tried simulation of my design, I always found that I spent a lot of time but got almost nothing and what I learned from University was not enough"** Edaboard
- Underservice: VERY HIGH — No comprehensive resource covers the full pipeline: antenna theory → simulation setup → meshing → solving → post-processing → measurement → correlation → discrepancy debugging
- Evidence: LinkedIn discussion: "The biggest challenge in antenna design is to make your antenna work flawlessly in its ultimate environment." LinkedIn MATLAB Antenna Toolbox and Remcom have isolated examples, MathWorks but no integrated tutorial exists
- Industry context: 970+ RF antenna engineer job postings in the US; ZipRecruiter employers seek "practical experience" they can't find

Tier 2: Significant gaps with moderate-to-strong demand

6. GPU acceleration for CEM solvers

- Demand: MODERATE-HIGH — NVIDIA spotlights GPU FDTD achieving 80× speedup; NVIDIA Developer gprMax offers CUDA engine; ScienceDirect LearnEMC Ansys Lumerical added GPU support in 2023 Ansys

- Underservice: EXTREME — **Zero** educational content on "how to write a GPU FDTD solver." All content is research papers or vendor documentation
- Evidence: GitHub projects (fdtdx with JAX, flaport/fdtd with PyTorch) demonstrate grassroots demand. Springer chapter on GPU FDTD reports 17× speedup but is paywalled academic content Springer

7. FEM for electromagnetics — practical implementation

- Demand: MODERATE-HIGH — FEM underpins HFSS (the most-demanded tool in job postings, **244 positions**, $97K–$190K salary) epsilonforge +2
- Underservice: VERY HIGH — No standalone video course or tutorial series teaches FEM implementation for EM. FEniCS has one magnetostatic example. Epsilonforge Jin's textbook is "more theoretical and lacks coding hints" per reviewers
- Evidence: Georgia Tech ECE 6380 covers node-based and edge-based FEM but as one segment of a broader course. Georgia Tech Georgia Tech The Nédélec edge element — essential for vector EM FEM — has no accessible tutorial anywhere

8. Practical validation and uncertainty quantification in CEM

- Demand: MODERATE-HIGH — An ACES paper by Andrew Drozd explicitly states: **"Concerns have been raised regarding the lack of well-defined methodologies to achieve CEM technique validations within a consistent level of accuracy"** DTIC
- Underservice: EXTREME — All content is in research papers (TU Darmstadt, Sandia, Colorado State). Zero tutorials exist
- Evidence: UQ research uses Polynomial Chaos and Kriging surrogate models, but no practitioner-accessible resource teaches these methods for CEM applications

9. Open-source CEM tool tutorials (Meep, OpenEMS, gprMax)

- Demand: HIGH — Commercial tools cost $50K–$90K per license. epsilonforge Ozeninc A PhD student noted Meep has **"an extremely steep learning curve — written for people with graduate-level physics mastery"**
- Underservice: HIGH — OpenEMS's community forum has been **down since 2023** (migrated to GitHub Discussions). Meep documentation is comprehensive but inaccessible to beginners. Readthedocs Only one Udemy course uses openEMS
- Evidence: EpsilonForge analysis notes "all-inclusive and cross-platform installation utilities are almost never provided" for open-source EM tools. Community workarounds include "rough estimations instead of simulations"

10. HPC parallelization of CEM codes

- Demand: MODERATE — Required for production 3D CEM; Meep supports MPI, Epsilonforge Palace is HPC-focused
- Underservice: VERY HIGH — No tutorials explain domain decomposition for EM, memory/compute scaling, or practical HPC deployment. Knowledge is siloed in research groups
- Evidence: Palace (AWS) is described as "notably the most challenging to use, with a steep learning curve that reflects its HPC focus — buckle up, it's a wild ride" epsilonforge Epsilonforge

Tier 3: Notable gaps with emerging or niche demand

11. Hybrid methods (FDTD-FEM, MoM-PO, FEM-BI)

- Demand: MODERATE — Critical for large-scale multi-physics problems; FEKO implements MoM-PO commercially
- Underservice: EXTREME — Virtually **zero** educational resources. No tutorials, no open-source implementations, no step-by-step guides. The most underserved topic by pure resource availability
- Evidence: MATLAB Antenna Toolbox has a hybrid MoM-PO solver MathWorks as a black box. Georgia Tech ECE 7380 briefly covers it. Georgia Tech gatech Otherwise, only research papers

12. EMC/EMI and signal integrity simulation using CEM methods

- Demand: MODERATE-HIGH — IPC SI course costs $1,600–$2,000; IPC Edge Training Cadence certification requires 92 hours. Cadence EMC compliance is mandatory for all electronics
- Underservice: HIGH — All content is vendor-specific (Ansys, Cadence, Keysight) or behind IEEE EMC Society paywalls ($29.95–$500 per video). No free, CEM-methods-based tutorial exists
- Evidence: Signal Integrity Journal provides articles but no simulation tutorials. PCB design rule content is abundant but doesn't explain underlying EM simulation methodology

13. RCS computation for complex geometries

- Demand: MODERATE — Defense/aerospace employers (Lockheed, Raytheon, Boeing) require RCS skills
- Underservice: HIGH — Canonical sphere problems are well-covered Flexcompute (OpenEMS, Meep, Tidy3D all have tutorials). Openems But **RCS for realistic targets with coatings and edge diffraction has zero accessible tutorials**
- Evidence: PyPOFacets (Physical Optics) on GitHub is the only open-source tool for complex geometry RCS. IEEE tutorial reviews exist but are paywalled

14. FDTD advanced topics (subgridding, dispersive materials, near-to-far-field transforms)

- Demand: MODERATE — Essential for production FDTD but not beginner-level
- Underservice: HIGH — Subgridding is "almost entirely confined to academic papers." Only one dedicated video lecture exists on numerical dispersion (Flexcompute FDTD101). Flexcompute PML implementation details have a few scattered resources Flexcompute but no comprehensive coding tutorial
- Evidence: Forum users specifically cite PML, meshing strategies, and dispersive material modeling as generating the most confusion

15. Photonics/nanophotonics simulation

- Demand: MODERATE-HIGH — Growing field driven by integrated photonics
- Underservice: LOW-MODERATE — **Best-served CEM niche** thanks to MIT's Meep, LearnEMC Epsilonforge Flexcompute's Tidy3D with FDTD101 lectures, and EMPossible's RCWA/PWE courses. EMPossible EMPossible Gap mainly in tool-agnostic pedagogy and advanced topics (nonlinear, quantum)
- Evidence: Flexcompute's free FDTD101 series with Jupyter notebooks and Meep's photonic crystal tutorials provide reasonable coverage

The market opportunity is real but fragmented

The CEM education market exhibits a striking pricing vacuum. At the bottom, free YouTube content and NPTEL provide theory-heavy introductions. Udemy offers **$10–$85 tool-specific tutorials** (CST button-clicking, HFSS basics) with ~15 relevant courses but zero on CEM algorithms. EMPossible occupies a lonely middle ground with paid MATLAB courses. EMPossible EMPossible Then the price leaps to **$595–$995 for COMSOL multi-day training** COMSOL COMSOL and estimated $1,000–$5,000 for Ansys/vendor training — all vendor-specific, teaching no transferable CEM knowledge. The gap between a **$15 Udemy course and $1,000+ vendor training** is enormous and underserved.

Job market data confirms demand: Glassdoor lists **127 "electromagnetics computational" positions**, Glassdoor ZipRecruiter shows **244 HFSS-related jobs** at $97K–$190K, ZipRecruiter and **970 RF antenna design positions** exist in the US. ZipRecruiter The median electromagnetic engineer salary is **$144,005/year**. Glassdoor Top employers include Apple, Boeing, Lockheed Martin, Raytheon, SpaceX, and Cadence. Indeed Jooble Industry analysis identifies a persistent talent gap: "Companies need engineers with specialized knowledge, and finding talent with the right combination of theoretical understanding and practical experience can be difficult." OpenCourser

No paid CEM-specific community or membership exists anywhere — no Discord, Slack, Patreon, or YouTube membership channel. The CEM community is fragmented across general EE forums (EDAboard, Reddit r/ECE) and expensive professional society memberships (IEEE, ACES). A **$15–$25/month CEM community** with expert Q&A, code libraries, and job boards would have no direct competitor.

Conservative market sizing suggests **$15–25 million annually** for CEM-specific education globally, with the adjacent RF/antenna/SI/EMC training market exceeding $100 million when including vendor training. Growth

drivers include 5G/6G proliferation, autonomous vehicle radar, defense modernization, and the emerging ML-CEM intersection.

What practitioners actually say they need

The industry-academic mismatch is stark. Universities teach Maxwell's equations theory; employers want HFSS proficiency and simulation-to-measurement correlation. An EDAboard user captures the frustration: "I always found that I spent a lot of time [on simulation] but got almost nothing and what I learned from University was not enough." Edaboard A LinkedIn contributor notes: "The biggest challenge in antenna design is to make your antenna work flawlessly in its ultimate environment. Designing an antenna in free space is easy, but integrating it in the whole system is the task." LinkedIn

Practitioners most frequently cite these missing skills: **simulation tool proficiency** beyond button-clicking (understanding what the solver does), **correlation between simulation and measurement** (knowing why results diverge), **system-level integration** (antenna-in-platform, co-site interference), **EMC/EMI compliance workflows**, and increasingly, **Python scripting for simulation automation**. The OpenCourser career guide identifies "a gap between the skills taught in traditional academic programs and the specific expertise needed for emerging technologies like 5G/6G, advanced semiconductor materials (GaN), or AI applications in RF." OpenCourser The Wireless Infrastructure Association recommends a "vendor-neutral training foundation" Wireless Infrastructure Associat… — which does not currently exist.

Conclusion: Where to build

Five opportunities stand out as having the strongest combination of demand, underservice, and feasibility. **First**, a Python-based CEM implementation course covering FDTD, MoM, and FEM from scratch would have zero direct competitors and serve both the academic and self-learner markets. **Second**, practical antenna simulation workflow content — from requirements through design, simulation, fabrication, and measurement correlation — addresses the #1 practitioner complaint and has no existing resource. **Third**, ML/AI for CEM tutorials sit at a uniquely high-growth intersection where research is racing ahead but education is entirely absent. **Fourth**, open-source tool tutorials with actual learning pathways (not just documentation) would serve the large population priced out of $50K+ commercial licenses. **Fifth**, a CEM-specific paid community would fill an empty niche and create a platform for distributing all of the above. The consistent thread across all gaps is that people don't just need more theory — they need the bridge from understanding Maxwell's equations to writing working code and getting simulation results that match reality. EMPossible
